(54) Obtention and analysis of odors from odor emitters

(57) An apparatus and a process for obtaining and analyzing aroma chemicals emitted from an aroma-emitting source are disclosed. The apparatus includes the use of one or more capillary tubes (10) which have on their interior surfaces an absorbent material, a suc-

tion device for drawing the aroma chemicals through the capillary tubes (10), and a connecting tube (12) which connects the capillary tubes (10) and the suction device.

EP 0 961 108 A1

Description

[0001] The present invention relates to obtaining odors from odor emitting objects. More Particularly, the present invention relates to an apparatus and process for acquiring odor(s) emitted from odor emitting objects.

[0002] The emission of odor(s) from objects has given rise to attempts to copy or to acquire odors of interest. For example, aromas from botanical sources, such as living flowers, leaves or other parts of living trees or plants, are sought after in the perfumery arts.

[0003] A technique for capturing and analyzing the scent of flowers is described in *Perfumes Art Science and Technology* edited by P.M. Müller and D. Lamparsky and summarized by R. Kaiser in *The Scent of Orchids*. The method disclosed involves placing a living flower, which is part of a living plant or tree, into an enclosed glass vessel. The glass vessel must be of suitable size and shape to permit the flower to be enclosed without damaging the plant or flower. Specially designed glassware is often required to accommodate particular types of flowers.

[0004] When such vessels are employed, the aroma chemicals surrounding a flower, i.e. the headspace, fill the vessel with a vapor phase. The headspace volatiles are drawn through an adsorption trap by means of a pump, over a period of 30 minutes to 2 hours. Adsorbents commonly employed in the trap are activated charcoal or special polymeric materials such as TENAX® (2,6-diphenylene polymer) or Porapak Q® (ethylvinylbenzene-divinylbenzene copolymer). The trapped aroma chemicals are eluted from the trap with a solvent, and injected into a gas chromatograph and analyzed by mass spectrometry (GC/MS).

[0005] Mookherjee *et al.*, U.S. Patent No. 5,369,978, discloses improvements in the above noted method, although essentially the same principles apply.

[0006] In addition, a technique using solid phase micro extraction (SPME) has been described by Mookherjee, *et al.*, *Perfumer and Flavorist* 23, pp. 1-11 (1998). This technique requires placing a single SPME needle, which is a 2-3 mm solid glass fiber coated with a high boiling point liquid adsorbent, in close proximity to a flower for 30 minutes to 60 minutes. The aroma molecules are adsorbed onto the needle-like glass fiber and are then analyzed by GC/MS.

[0007] Great difficulty, however, has been encountered in attempting to collect scents from certain aroma sources using conventional aroma collecting devices. Special glassware for enclosure of flowers can be inconvenient to use, particularly when the flowers are not readily accessible. Also, they can be awkward to carry to and from remote locations. The rain forest, for example, has a cornucopia of fragrant scent-emitters. However, flowers are often at the end of high slender branches in the forest canopy and are difficult to reach.

[0008] Additionally, it is very difficult to attach the conventional collecting devices to the outer branches of

trees. Often they do not support the weight of either a person or the equipment employed to collect a sample, particularly in view the length of time required, which can thwart efforts to obtain aromas from some sources.

[0009] With respect to the SPME technique, SPME needles are very delicate. The single needle employed to obtain the scent may break at any time in dense canopy. In fact, more often than not, such needles break during capture in such an environment.

[0010] The present invention addresses these problems by providing an apparatus for obtaining odor(s) emitted from an odor emitting source. The apparatus of the present invention includes an adsorption unit having at least two openings, which may be one or more capillary tubes. The interior surfaces of the tubes comprise an adsorbent material for adsorbing odor chemicals. A suction device for drawing odor chemicals into the adsorption unit, is positioned for and connected to the tube assembly and a connector connects the tube assembly and the drawing device.

[0011] The invention also provides a process for obtaining or capturing odor chemicals. The process includes placing an adsorption unit, which comprises on its interior surface an adsorbent material for trapping aroma chemicals, in proximity to an aroma-emitter, and drawing aroma chemicals into an opening of the adsorption unit with a gas drawing means which is operably connected to the adsorption unit.

[0012] Further, the invention allows for the thermal desorption of adsorbed sample, cryogenic focusing, and resolution and identification odor components by GC/MS.

[0013] It is an object of the present invention to provide an apparatus for obtaining aroma chemicals from, in particular, difficult to reach aroma emitters.

[0014] It also is an object of the present invention to provide an apparatus which is readily portable and is durable for obtaining aroma chemicals from, in particular, a dense canopy.

[0015] It also is an object of the present invention to provide a process for obtaining aroma chemicals from, in particular, difficult to reach aroma emitters.

[0016] It is a further object of the invention to provide a process for obtaining aroma molecules which facilitates a short capture time.

[0017] The apparatus for obtaining odors includes an adsorption unit, a suction device for drawing the odor chemicals into the adsorption unit, and it can have a connector for operably connecting the adsorption unit and the suction device.

[0018] The adsorption unit has an opening for receiving odor chemicals and an opening displaced away from the first for drawing the odor chemicals through. The adsorption unit can be a tube or preferably, a plurality of tubes. A plurality of capillary tubes are the most preferred type of adsorption unit. As used herein, the term odor includes, but is not limited to aromas, as for example, fragrant scents.

[0019] The type and dimensions of the tubes of the adsorption unit may vary. For example, a single tube having a plurality of crossing wall portions contained within the tube are considered to be an equivalent alternative to the plurality of capillary tubes. Similarly, tubes having concentric tubes of decreasing diameter contained within a tube also are considered to be equivalent, because of the favorable surface area exposed to odor chemicals. Generally, the inside diameter of the capillary tube ranges from about 0.07 mm to about 1.0 mm and more preferably from about 0.75 mm to about 0.9 mm.

[0020] The interior surface(s) of the adsorption unit are coated with an adsorbent material for adsorbing odor chemicals from the air to the stationary material. It is also contemplated that the adsorption unit integrally have interior surface(s) of an adsorbing material. As used herein, an adsorption unit which comprises an adsorbent material on its surface(s) encompasses both of these situations.

[0021] The adsorbent employed can vary depending on the odor chemicals sought to be obtained. Generally adsorbent materials, e.g., charcoal, may be used. Preferably, highly adsorbent materials of differing polarity are used to ensure that all aroma chemicals are obtained. The adsorbent material can be selected from the group consisting of a polar adsorbent, a non-polar adsorbent, an intermediate polarity adsorbent, and any combination thereof. A portion of the capillary tubes may be internally coated with a polar adsorbent, another portion with a non-polar adsorbent, and another portion with an intermediate polarity or neutral adsorbent. Examples of adsorbent materials that are useful in the practice of the invention are Carbowax 20-M as a polar phase adsorbent, methyl silicone as a non-polar adsorbent, and phenyl methyl silicone and polyacrylate as intermediate polarity solvents. These materials are coated on the inside of the capillary tube to a thickness of from about 0.1 μm to about 1.25 μm , preferably from about 0.1 to about 0.7 μm , and most preferably from about 0.15 μm to about 0.7 μm .

[0022] In addition, while preferred tubes for obtaining flower aromas are capillary tubes made from fused silica, alternative tubes may be made of different types of materials which may not be required to be coated *per se* or which may be made, for example, metal of a glass, a tempered glass, a polymer or a polymer composite.

[0023] The length and number of tubes depends upon the scent emitting source. In general, at least three tubes of each selected phase are used. The total number is such that the bundle of tubes will fit inside a tube from which sample is drawn by the selected thermal desorption device. In the case of the Gertsel Thermal Desorption System TDS 2, the bundle must fit into a 6 mm external diameter tube. The length of the capillary bundle is from about 5 mm to about 120 mm, usually from about 15 mm to about 120 mm, and more preferably from about 20 mm to about 40 mm.

[0024] The capillary bundle is held within the distal end of the connecting tube in an air-tight manner. The connecting tube is of a flexible material such as PTFE (Teflon). The diameter of the connecting tube should be such that the bundle of capillaries fit snugly within. To ensure an air-tight seal, a fastener is affixed around the connecting tube at a location where the capillaries are within. Typically, the connecting tube is made of heat-shrink tubing, and heat is applied to the area around the fastener.

[0025] The capillary bundle can be suspended in proximity to the aroma emitting source by holding the connecting tube so that the free end of the capillary tubes are held in place, usually over a flower. When the opening of the capillary tubes which is not attached to the connecting tube is placed in proximity with an aroma emitter, the suction device is activated and the aroma chemicals are drawn through the coated capillary tubes from about 2 to about 15 minutes. A 2 to 5 minute collection time is usually sufficient, particularly for the major components. A 5 to 15 minute collection time may be used for components that are present in smaller amounts. The suction device is any device which draws a fluid such as a gas, preferably the headspace air, through each coated capillary tube at a controlled rate. For example, the suction device can be a pump, such as, for example, a piston pump, a vane pump, a diaphragm pump, a peristaltic pump or can be a fan. Consequently, a sufficient amount of odor chemicals are adsorbed onto the adsorbent material in a relatively short amount of time to permit analysis of the odor components.

[0026] Especially useful are suction devices that do not let the gas being drawn through the capillaries come into direct contact with the suction device itself, thus avoiding contamination. An example of such a suction device is a diaphragm pump that is capable of pumping from 10 - 100 ml gas per minute. The pump may be operable by conventional means such as by electric current or battery. For trips to remote locations for scent capture, a battery operated pump is used. The pumping rate of the suction device is adjusted using a flow metering device so that the amount of gas passing through the array of capillary tubes in a given time can be measured. Thus, air may be drawn or moved into and through the coated tubes from about 2 to 15 minutes or longer, if desired.

[0027] Advantageously, the apparatus has a support for supporting or securing the capillary tubes, and additionally, a housing sheath within which the plurality of capillary tubes are disposed such that they are freely moveable with the connector. Also advantageously, the apparatus includes a means for extending the tube assembly beyond the end of the housing sheath for collection of odor chemicals.

[0028] Preferably, the connecting tube holding the capillaries is supported or held by a support such as a rigid rod. The support is of fairly rigid material such as

glass, metal, wood or stiff polymeric materials. The support can be any practicable length for reaching odor sources in high branches. Of great use for also reaching aroma sources that are hard to access is a light weight extendible tubular pole which permits the collection device to be extended with the arm portion angled such that the distal end of the device reaches over a flower. The pole can be made of aluminum or the like for a sturdy, light-weight construction. When using an extendible pole, the support can be affixed to the distal end or integral therewith. In addition, the pole can be collapsed for easy transport.

[0029] The extendible pole can in practicality be up to 8 feet long when fully extended. It is advantageous for the extendible pole to be foldable for ease of carrying to about a 3½ feet length. There should be at least one hinging arm portion for extending at a different angle from that of the adjacent portion. If there is only one arm portion, it should be at the distal end for extending the capillaries. How far the pole is extended and at what angle, if any, the arm is extended, depends upon the distance and accessibility of the flower.

[0030] Any extension pole used accommodates the connecting tube either alongside or within the pole. To accommodate the connecting tube within the pole, the pole should be hollow, with enough room in the hollow space of the tubing to run through. There must also be sufficient play for the connecting tube at the hinging points when the arm is angled. It is preferable, however, to run the connecting tube alongside the extendible pole, so that the tube need not be flexed as much by the hinging portion of the arm.

[0031] Whether the support at the distal end is integral or attached to the pole, the support itself must support or hold the connecting tube which holds the bundle of capillaries. The support is preferably tubular with a sufficient hollow interior area to accommodate the connecting tube. The support can be attached to the pole such that it can swivel, to provide even further flexibility for accessing a particular flower in dense foliage.

[0032] The capillary bundle can be extended is to push the connecting tube from where the operator stands toward the direction of the capillary bundles. The connecting tube slides along or within the support and the capillary tubes are thus extended outward. The connecting tube can be pulled back to retrieve the capillaries back into the support. Any manner of moving the connecting tube in the direction of the aroma source is deemed to be within the scope of the present invention.

[0033] It is preferable to protect the capillary bundle while it is being extended and maneuvered into position relative to the desired aroma-emitter. We have found that it is desirable to first insert the connecting tube holding the bundle into a housing sheath of semi-rigid material such as nylon which is substantially friction-free with respect to the connector. It is suitable for the housing sheath to be tubular and it is connected or attached to the support or it can be connected or

attached within a tubular support. A connecting tube of PTFE (Teflon), for instance, must be freely moveable along the surface of the sheath. Accordingly, the connecting tube holding the capillaries can be extended beyond the end of the housing sheath when in proximity to a flower for collection.

[0034] Where the support is tubular and the sheath is attached therein, the support provides the actual barrier or protective covering to shield the capillary tubes from damage. Yet the sheath which facilitates ready deployment of the capillaries after the apparatus has been extended into position through branches, etc., contributes to the protection of the capillaries.

[0035] It is also contemplated that the support can be prefabricated with an inner surface of sheath material.

[0036] In the preferred embodiment, the connecting tube within the housing sheath runs alongside the extendible pole. Fasteners can be used at one or more locations along the pole to fasten the sheath to the pole. The housing sheath can be run along the extendible pole beyond any hinge points, or preferably, into the support. This configuration advantageously permits free movement of the connecting tube by the operator pushing the tube at the proximal end of the housing sheath.

[0037] When a long pole is used with an attached support at the distal end, the housing sheath can be disposed on or in the support. Preferably, the housing sheath holds the connecting tube within, for the length of the pole. For a hollow extendible pole, the housing sheath runs along its exterior. As the housing sheath readily permits movement of the connecting tube, the connecting tube slides easily forward to extend the tubes for collection when the housing sheath is affixed alongside or throughout the entire length of the pole. It is suitable, though, to affix the housing sheath for about 75% of the length of the pole, where the sheath runs short at the proximal end of the pole.

[0038] The capillary bundle containing the trapped aroma chemicals is removed and carefully stored for subsequent processing. The aroma chemicals trapped within the capillaries of a bundle are then placed into a thermal desorber, for example, the Gertsel TDS 2. The desorbed volatiles are then transferred, using an inert gas such as helium at a flow rate of from 5 - 20 ml per minute, into a cryogenically cooled inlet that uses liquid nitrogen as coolant. The cryogenic focused materials are then analyzed directly by gas chromatography using an instrument such as a Hewlett Packard 6890 gas chromatograph equipped with a methyl silicone capillary column (0.125 mm x 60 meter), and a mass spectrometer such as the Hewlett Packard 5973 mass spectral detector. Quantitative as well as qualitative analysis of the fragrance components can be performed. The analysis is simplified as the sample can be processed from the desorber through the mass spectrometer by the devices all connected in-line. We have surprisingly found that the process provides data of at least the same quality as the less practical existing

methods.

[0039] As the present invention permits the capture of the headspace volatiles of a flower high up in the canopy, it will be apparent that when capture is performed in dense canopy, aroma molecules from adjacent aroma-emitters may also be captured. In this case, the captured molecules can represent some combination of aroma molecules from two or more aroma-emitting sources. Analysis of the adsorbed aroma chemicals from more than one source can identify desirable scent combinations.

[0040] Further details of the invention are described with the help of the following figures.

Figure 1 illustrates a sectional view of a capillary tube bundle held within a connecting tube.

Figure 2 illustrates the capture of aroma chemicals with a collection apparatus employing an extendible arm and a support attached thereto.

Figure 2a illustrates the support of Figure 2 in cross-section.

Figure 3 illustrates apparatus for obtaining odors.

Figure 4 illustrates apparatus for analyzing odors.

Figure 5 illustrates a GC graph of resolved chemical components from a 2 minute aroma capture.

Figure 6 illustrates a GC graph as in Figure 5, where aroma capture was for 5 minutes.

Figure 7 illustrates a GC graph as in Figures 5 and 6, where aroma capture was for 10 minutes.

[0041] As illustrated in Figure 1, a bundle of capillary tubes 10 are held by connecting tube 12. The capillary tubes of bundle of capillary tubes 10 are coated on their inner surfaces (not shown) with adsorbent material(s) of various polarities. Fastener 14 is fastened around connecting tube 12.

[0042] Capillary bundle 10 is connected to a pump (not shown in Fig. 1) by connecting tube 12.

[0043] As illustrated in Figure 2, aroma chemicals are obtained with a collection device employing support 26 which is attached by wing nut 18 to extension arm 20. Extension arm 20 represents the distal portion of an extension device. Wing nut 18 secures the top side of support 26, which is shown as hollow or tubular throughout. Support 26 can swivel in this embodiment.

[0044] Capillary bundle 10 is shown over flower 24 collecting aroma chemicals. Connecting tube 12 is shown extended out from housing sheath 16. Housing sheath 16 runs within support 26 and emerges from aperture 28 of support 26 and runs alongside support 26 and extension arm 20. Fasteners 30 allow for loose

fastening of housing sheath 16 to both support 26 and extension arm 20.

[0045] Figure 2a illustrates the support of Figure 2, in cross-section. Housing sheath 16 is within support 26. Within housing sheath 16 is connecting tube 12.

[0046] Figure 3 illustrates a system for the collection of odors. A collection device is shown with extension device 40 having extension arm 20 and with a suction device 42 which is preferably a diaphragm pump. Connecting tube 12 runs through housing sheath 16. Housing sheath 16 is within support 26 at its distal end (not shown here). Housing sheath 16 runs from aperture 28 of support 26 along the support and extension device 40. Connecting tube 12 emerges from housing sheath 16 and is operably connected to pump 42.

[0047] Figure 4 illustrates the desorption and analysis of the captured aroma chemicals. After capture of aroma chemicals, the capillaries 10 are placed into thermal desorber 44. The desorbed volatiles are transferred into cryogenically cooled inlet 46. The cryogenically focused materials are then analyzed by GC/MS instrument 50.

Example 1

[0048] Scent was captured using three separate capillary bundles, each bundle having capillaries coated with Carbowax 20M[®] and capillaries coated with methyl silicone. By use of the aroma collection apparatus and method of the present invention, the aroma of a Hyacinth was collected. For the first capillary bundle, exposure of the coated capillaries to the headspace was for 2 minutes. For the second bundle, the collection time was 5 minutes and for the third, the bundle was exposed for 10 minutes.

[0049] Each bundle of tubes was placed in the thermal desorber. The samples were desorbed, cryogenically focused and then analyzed on a gas chromatograph. The gas chromatograph utilized a methyl silicone capillary column (0.125 mm x 60m), a helium gas flow rate of 1.5 ml/min and was programmed from 40°C to 250°C at a 4° per min rate.

[0050] Figure 5 is a graphical display of adsorption determined by GC for the first capillary bundle. The intensity of resolved odor chemicals is shown as a function of time. It has been determined that a sufficient amount of all components were adsorbed in sufficient quantity over a period of 2 minutes such that the components could be identified by GC/MS.

[0051] Figure 6 is a graphical display as in Fig 5, although for the second capillary bundle. In comparing the relative intensities of corresponding peaks from Figures 4 and 5, it can be seen that the intensity of the peaks is greater for a 5 minute adsorption time than for a 2 minute adsorption time. All peaks were identified with a mass spectral library and cross-referenced.

[0052] Figure 7 is also a graphical display as in Figures 5 and 6, although for the third capillary bundle. In

comparing peak intensities, it can be seen that a greater amount of the aroma components can be adsorbed in 10 minutes time then for 2 or 5 minutes.

[0053] While the invention has been illustrated and described with respect to illustrative embodiment and modes of practice, it will be apparent to those skilled in the art that various modifications and improvements may be made without departing from the scope and spirit of the invention. Accordingly, the invention is not to be limited by the illustrative embodiments and modes of practice.

Claims

1. An apparatus for obtaining or capturing odor chemicals comprising:
 - an adsorbing unit comprising an interior surface of an adsorbent material; a suction device (42) for drawing the odor chemicals into the unit; and a connecting tube (12) which connects the unit and the suction device (42).
2. The apparatus according to claim 1 wherein the adsorbent material is selected from the group consisting of a polar adsorbent, a non-polar adsorbent, an intermediate polarity adsorbent, and any combination thereof.
3. The apparatus according to claim 2 wherein the polar adsorbent is Carbowax 20.
4. The apparatus according to claim 2 wherein the non-polar adsorbent is methyl silicone.
5. The apparatus according to claim 2 wherein the intermediate polarity adsorbent is selected from the group consisting of phenyl methyl silicone and polyacrylate.
6. The apparatus according to claim 1 wherein the adsorption unit is one or more capillary tubes (10).
7. The apparatus according to claim 6 wherein the adsorption unit is a plurality of capillary tubes (10) which may be disposed such that they are freely movable.
8. The apparatus according to claim 7 wherein the plurality of capillary tubes (10) consist of tubes coated with polar adsorbent, tubes coated with non-polar adsorbent and tubes coated with intermediate polarity adsorbent.
9. The apparatus according to claim 1 wherein the suction device (42) is a diaphragm pump.
10. The apparatus according to claim 1 where the con-

necting tube (12) is made from PTFE.

11. The apparatus according to claim 1 further comprising a support (26) for supporting the adsorption unit, wherein the support (26) is made from a rigid material selected from the group consisting of glass, metal, wood and stiff polymeric materials.
12. The apparatus according to claim 11 wherein the support (26) is an extendible tubular pole.
13. The apparatus according to claim 11 further comprising a housing sheath (16) which is attached to the support (26) and which holds the connecting tube (12) and the adsorbing unit therein such that they are freely moveable.
14. The apparatus according to claim 13 wherein the housing sheath (16) is made from a semi-rigid material, preferably made from nylon.
15. The apparatus according to claim 13 further comprising means for extending the adsorbing unit beyond the end of the housing sheath (16) for collection or odor chemicals.
16. The apparatus of any one of the claims 1 to 15 used for analyzing the odor chemicals emitted from an odor-emitting source, comprising:
 - the connecting tube (12) which connects the plurality of capillary tubes (10) and the suction device (42) and provides an air-tight seal there between;
 - a thermal desorber (44) disposed to hold the plurality of capillary tubes (10), for thermally desorbing odor chemicals trapped within;
 - a cryogenic focusing device; and
 - a gas chromatograph equipped with a mass spectrometral detector.
17. The apparatus according to claim 16 wherein the thermal desorber (44) is connected in-line to the cryogenic focusing device.
18. A process for obtaining odor chemicals from an odor-emitting source by using the apparatus according to any one of the claims 1 to 17 comprising:

placing the plurality of capillary tubes (10) in proximity to an odor-emitter;

drawing the odor chemicals into the capillary tubes (10) with a suction device (42) which is

operably connected to the plurality of capillary tubes (10) for from 2 to 15 minutes.

19. The process according to claim 18 further comprising:

5

desorbing the odor chemicals from the plurality of capillary tubes (10), to provide desorbed odor chemicals;

10

cryogenically focusing the desorbed odor chemicals to provide cryogenically focused odor chemicals; and

analyzing the cryogenically focused odor chemicals by a gas chromatograph equipped with a mass spectrometral detector.
